

A

Standard-inoculum arm, three flasks, both platings

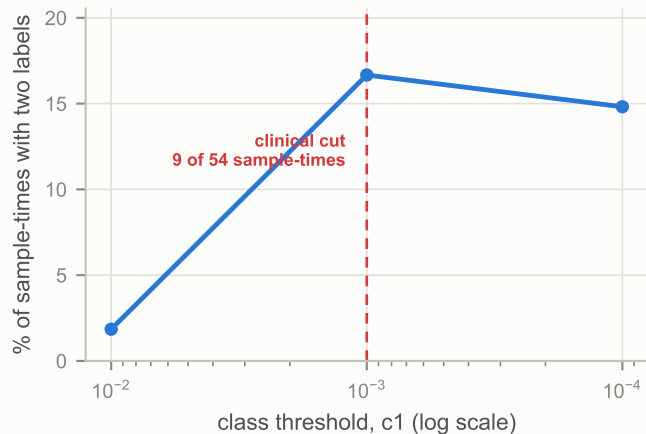

Filled points are measured counts; open points sit on the assay floor and are censored, not measured -- the line to a censored point is drawn for continuity only.

B Same flask, same afternoon, two ceilings

Every flask reaches four logs at 100 µL and falls short at 10 µL. The plated volume decides, not the drug.

C How often one culture gets two labels

Swept across every threshold; the vertical line is the cut Section 2 actually uses for the low/medium boundary.
